

EMIF Deliverable 2.3: Definition of extreme phenotypes based on cognitive decline

Executive summary

Executive Summary

Decrease in hippocampal volume (HV) mirrors the progression of Alzheimer's disease (AD). The ability to predict the change in the HV is of interest both for clinical diagnostics and for pharmaceutical industry.

The objective was to develop a model for predicting the change in HV during 24 months using data measured at the baseline.

Prediction performance of various models was assessed and this deliverable describes the results obtained.
