

EMIF Deliverable 5.4: Identify potential targets for drug development and diagnostic tests which meet standard clinical sensitivity and specificity criteria

Executive summary

Executive Summary

The work in WP5 has identified a set of proteins (CCL18, S100A4), metabolites (mannose) and lncRNAs in human white adipose tissue that are linked to metabolic complications of obesity. Only CCL18 and mannose are present in the circulation. They have therefore been carried forward for additional assessments as biomarkers for metabolic complications in larger cohorts in WP6.
